Process Definition Document (PDD)

Project: Regulatory Compliance Automation

Document purpose: Describe the current business need, process scope, rules and expected outcomes for automating regulatory notice monitoring using Automation Anywhere A360.

1. Business Background

The legal and tax teams need to monitor government portals for regulatory notices that may require action from the organization. Manual checking can be time-consuming and may lead to a notice being missed or identified late. The proposed automation checks the agreed portals every day, captures relevant notices, maps them to the appropriate business or tax identifier, and shares a daily status report with leadership.

2. Objectives

- Automate daily retrieval of notices from the government portals approved by the business.
- Reduce the chance of missed notices and improve the reliability of compliance monitoring.
- Apply agreed UID mapping rules so notices can be associated with the correct entity, account or identifier.
- Provide a daily compliance status report to the designated stakeholders.
- Maintain an audit trail of checks, retrieved notices, exceptions and report delivery.

3. Scope

In scope

- Scheduled daily execution of the Automation Anywhere A360 bot.
- Accessing the approved government portals using authorized credentials and permitted access methods.
- Searching or retrieving notices using the agreed identifiers and date/status filters.
- Extracting relevant notice details and applying UID mapping rules.
- Recording results, identifying exceptions and producing a daily status report.
- Notifying the agreed distribution list when the report is ready or when the run requires attention.

Out of scope

- Interpreting the legal meaning or urgency of a notice beyond the business-approved classification rules.
- Drafting, approving or submitting responses to government notices.
- Changing source data or correcting identifier mismatches without business approval.
- Monitoring portals that have not been approved and tested for this automation.
- Guaranteeing portal availability or eliminating failures caused by external websites.

4. Stakeholders and Responsibilities

Role	Responsibility
Legal team	Defines legal notice categories, review requirements and escalation rules.

Tax team	Defines tax portal checks, identifiers and business rules for tax-related notices.
Business / process owner	Approves scope, schedules, report format and acceptance criteria.
RPA developer / support	Builds, tests, deploys and supports the A360 automation.
IT / security	Approves access, credential handling, runtime environment and logging.
Leadership / report recipients	Reviews the daily compliance status and follows up on exceptions.

5. Inputs and Outputs

Type	Details
Inputs	Approved portal URLs; authorized credentials; UID/entity mapping file or source; search criteria; portal-specific rules; report distribution list.
Retrieved data	Notice/reference number, portal/source, entity or UID, notice date, due date when available, category/status, retrieval timestamp and source link.
Outputs	Daily compliance status report, detailed notice register, execution log and exception list.
Delivery	Approved shared location and/or email distribution list, as agreed with the process owner.

6. High-Level Process

1. Start the bot at the approved daily schedule.
2. Load configuration, portal list, UID mapping data and required credentials from approved secure sources.
3. Validate that required configuration and input data are available.
4. Open each approved portal and complete the agreed search for each relevant identifier.
5. Retrieve available notices and capture the required fields.
6. Normalize the retrieved information and map each notice to the appropriate UID/entity.
7. Check for duplicates and classify records using the agreed business rules.
8. Record successful checks, no-notice results, portal errors and mapping exceptions.
9. Generate the daily summary and detailed notice register.
10. Deliver the report to the approved recipients and save the run logs.
11. Close the run with a success, partial-success or failure status; alert support if intervention is required.

7. Business Rules

- The bot must check only portals and identifiers approved by the process owner.
- A notice should be considered new only after comparison against the agreed unique key, such as portal + notice/reference number + entity UID.
- If UID mapping is missing or ambiguous, the bot must flag the record for manual review rather than guessing the entity.
- If a portal is unavailable, the bot must log the portal, time and error and continue with other portals where safe to do so.
- A successful login or page load alone must not be treated as proof that the portal search completed successfully.
- The report must distinguish between 'no notices found', 'check completed', 'check failed' and 'manual review required'.
- The bot must not submit, acknowledge or respond to a notice unless that action is separately approved and documented.

8. Exceptions and Escalation

Scenario	Expected handling
Portal unavailable / timeout	Retry according to the approved retry policy; log the failure; continue with other portals where possible; flag the portal as not checked.
Login or access failure	Stop actions requiring that session, log a sanitized error and alert support. Do not expose passwords in logs.
UID not mapped	Place the notice in the exception list for legal/tax review; do not auto-assign an entity.
Duplicate notice	Avoid duplicate reporting based on the agreed unique key; retain an audit record of the detection.
Unexpected page/layout change	Capture a safe diagnostic log or screenshot if policy permits; stop the affected transaction and alert support.
Report delivery failure	Save the report to the approved location, log the delivery error and notify support through the fallback route.

9. Assumptions and Dependencies

- The business will provide the final portal list, identifiers, mapping data and notice classification rules.
- The organization has permission to access the portals and automate the agreed retrieval steps.
- Portal access methods and terms permit the proposed automation; CAPTCHA or other controls will not be bypassed.
- Credentials will be stored and accessed using approved enterprise credential management.

- The report recipients, delivery channel, run schedule, retry limits and retention period will be confirmed before production.

10. Acceptance Criteria

- The bot runs at the agreed daily schedule and records the outcome of every configured portal check.
- For test cases with known notices, the bot retrieves and records the required fields accurately.
- UID mapping follows the approved rules and ambiguous cases are routed to manual review.
- Duplicate detection works for the agreed unique key.
- The daily report clearly separates completed checks, no-notice results and failures/exceptions.
- Reports and logs are saved and delivered to the approved destinations.
- No passwords or unnecessary sensitive data are exposed in logs or reports.

11. Items to Confirm Before Build / Sign-off

- Exact government portals and portal-specific search steps.
- Authoritative UID mapping source, update frequency and ownership.
- Required fields and classification logic for each portal.
- Run time, time zone, retries, alert recipients and fallback process.
- Report template, distribution list, storage location and retention policy.
- Security approvals, test accounts, environment details and production support ownership.
